DEMONSTRATE DIFFERENT NUMBER DATA TYPES IN PYTHON

AIM:

To demonstrate different number data types in python.

ALGORITHM:

STEP 1: Start the program.

STEP 2: Assign an integer value and print its type.

STEP 3: Assign a float value and print its type.

STEP 4: Assign a complex value and print its type.

STEP 5: Print the values of all three variables.

STEP 6: Display their data types using type()

STEP 7: Stop the program.

CODING

#Integer type

age=25

print(age) **OR** print(“age:”, age)

print(type(age)) **OR** print(“Type of Age:”, type(age))

#Float type

height=60.5

print(height) **OR** print(“height:”, height)

print(type(height)) **OR** print(“Type of height:”, type(height))

Complex type

A=3+5j

print(A) **OR** print(“A:”, A)

print(type(A)) **OR** print(“Type of A:”, type(A))

OUTPUT

age: 25

Type of age: <class 'int'>

height: 60.5

Type of height: <class 'float'>

A: (3+5j)

Type of A: <class 'complex'>

RESULT:

Thus, the program to demonstrate different number data types in python is executed successfully.
